

Extra Lecture: Privacy on the Web
(History stealing, Fingerprinting, DNT, etc.)

Webonomics

- The Web has allowed **free**, convenient services to proliferate
 - Google, Android
 - Facebook, Instagram
 - Millions of smartphone apps
- Who pays for the costs of all these services?
 - You do.
 - Not in cash, but in personal information

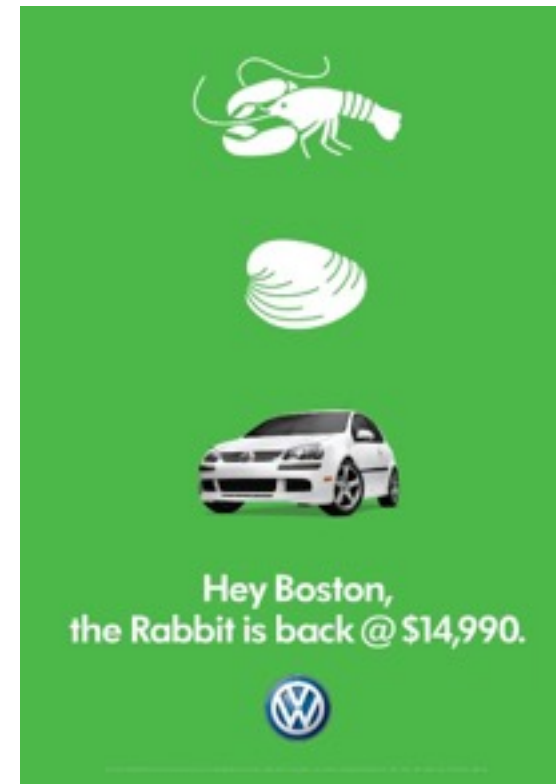

“If you are not paying for it, you're not the customer; you're the product being sold” - Andrew Lewis, 2002

Advertising on the Web

- By and large, advertising provides the money for web services and apps
 - 90% of Google's \$6 Billion in revenue came from ads in 2014

Pre-Web advertising → Branding

Web advertising → Targeting

Your Personal Information is Valuable

How is this information collected, shared, and used for targeted advertising?

Tracking

Cookies, Flash Cookies, E-tags, Evercookies, Supercookies!

DNT

Fingerprinting

IP Address Tracking

- IP address is the most basic mechanism for tracking on the Internet
 - Everybody must have an IP address
 - Every packet you send contains your IP address
 - Your IP address remains relatively constant over time
- However, IP address is not as useful as it once was. Why?
 - NATs are ubiquitous; multiple people behind a single IP
 - Cell networks employ many layers of NATs and proxies
 - Users split their time across multiple devices with separate IPs

Cookies

- Allows servers to store state on client web browsers
 - Originally, invented for storing authentication information (session cookies)
 - Today, routinely used to implement tracking cookies
- Tracking cookies are so pervasive that they are now legislated
 - EU e-Privacy Directive (Cookie Law)
 - Requires that sites disclose if they use cookies and what they are used for
 - Users must opt-in before cookies can be set
 - Google was fined \$22.5 Million by the FTC for circumventing cookie restrictions in Safari
 - Safari did not accept third-party cookies by default...
 - ... unless they were received after a POST
 - Google used Ajax to send a POST to circumvent Safari's restriction

Third-party Cookie Tracking

```
<script src="http://  
www.googletagservices.com/tag/js/  
gpt.js?id=yelp">
```

yelp.com

Google (and its services like Doubleclick) are embedded in 40-60% of all web pages

Cookie: _gads=saf9vDFDsP0w3

Set-Cookie: _gads=saf9vDFDsP0w3

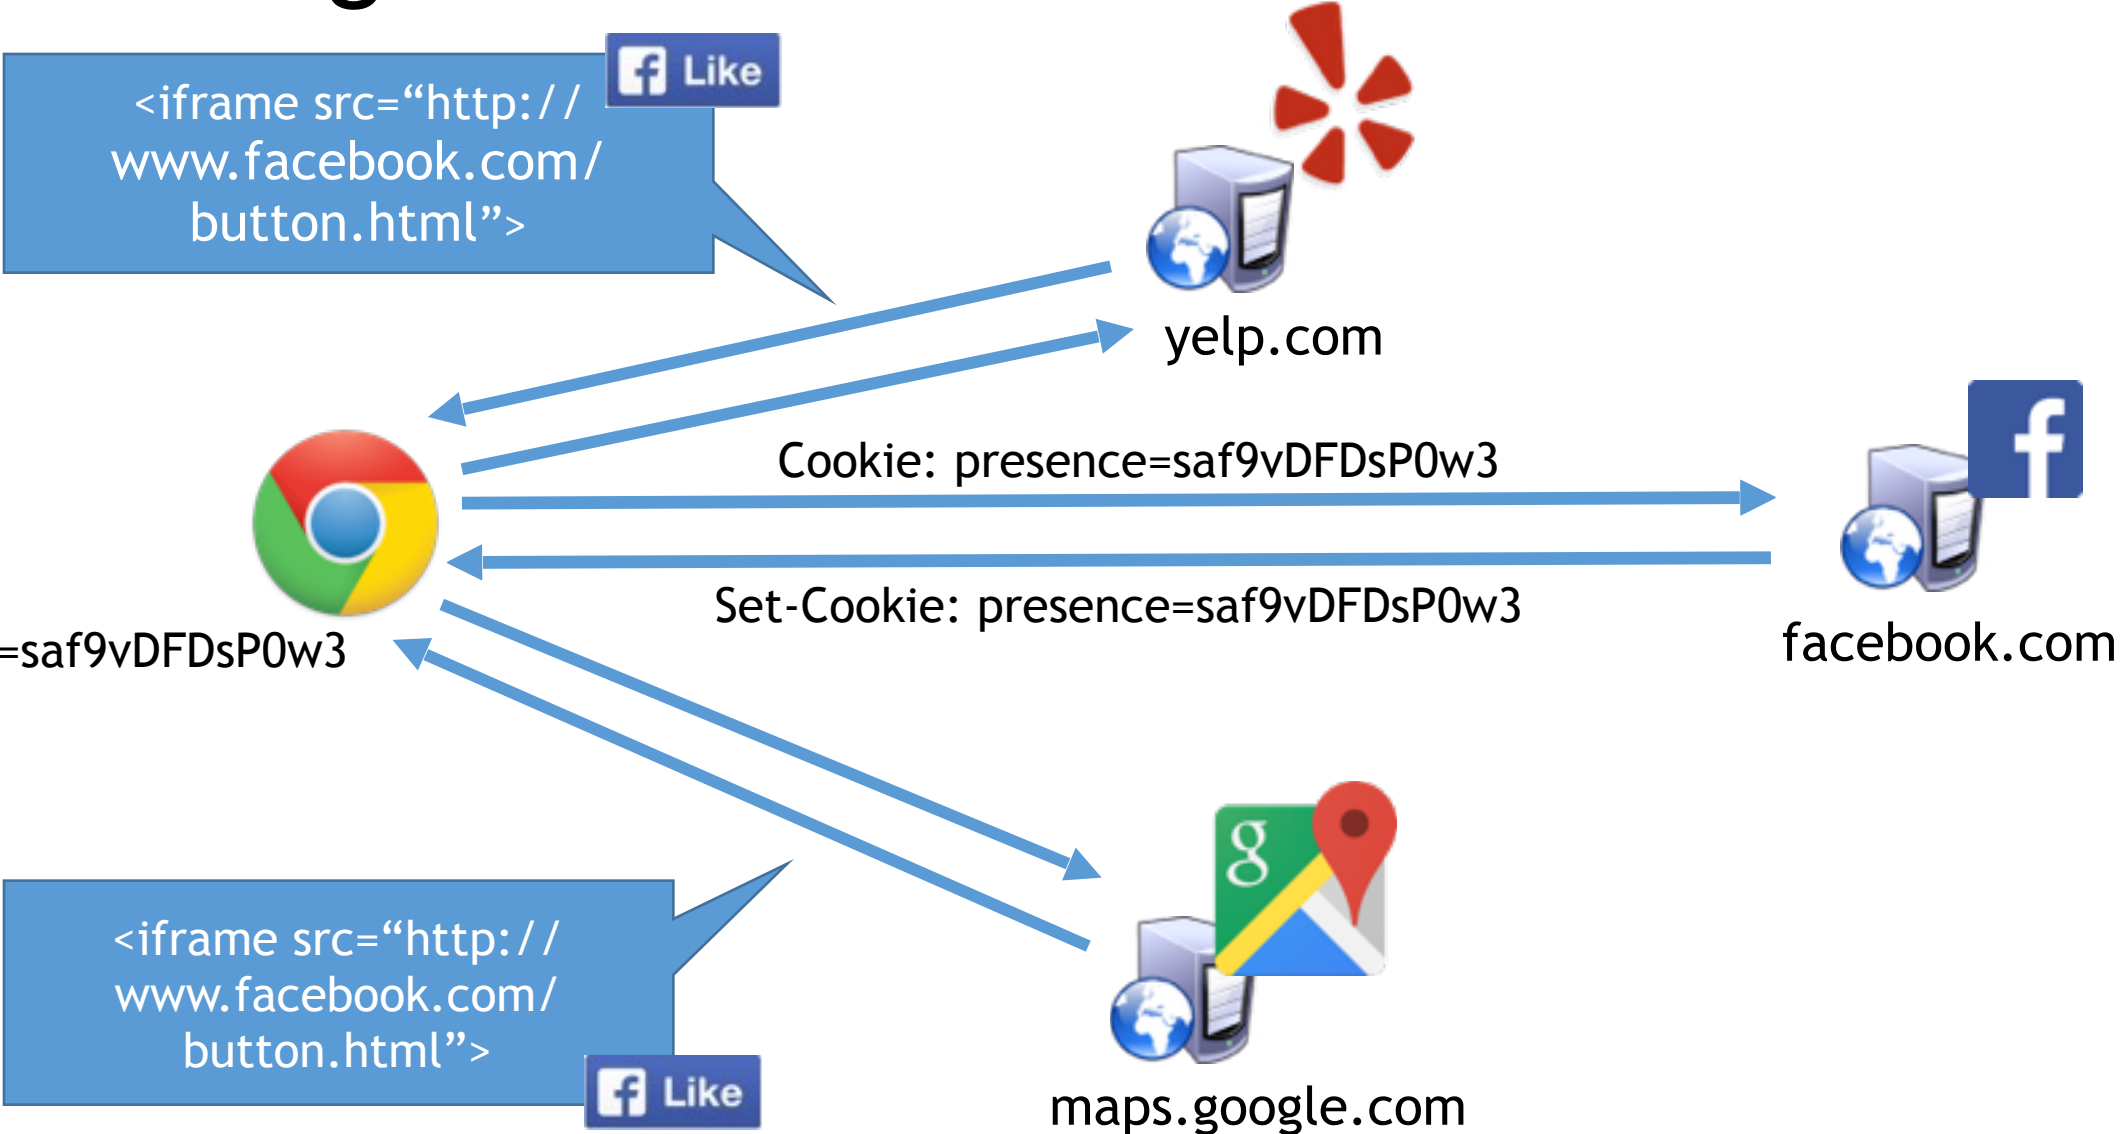

Cookie: _gads=saf9vDFDsP0w3

```
<script src="http://  
www.googletagservices.com/tag/js/  
gpt.js?id=gmaps">
```

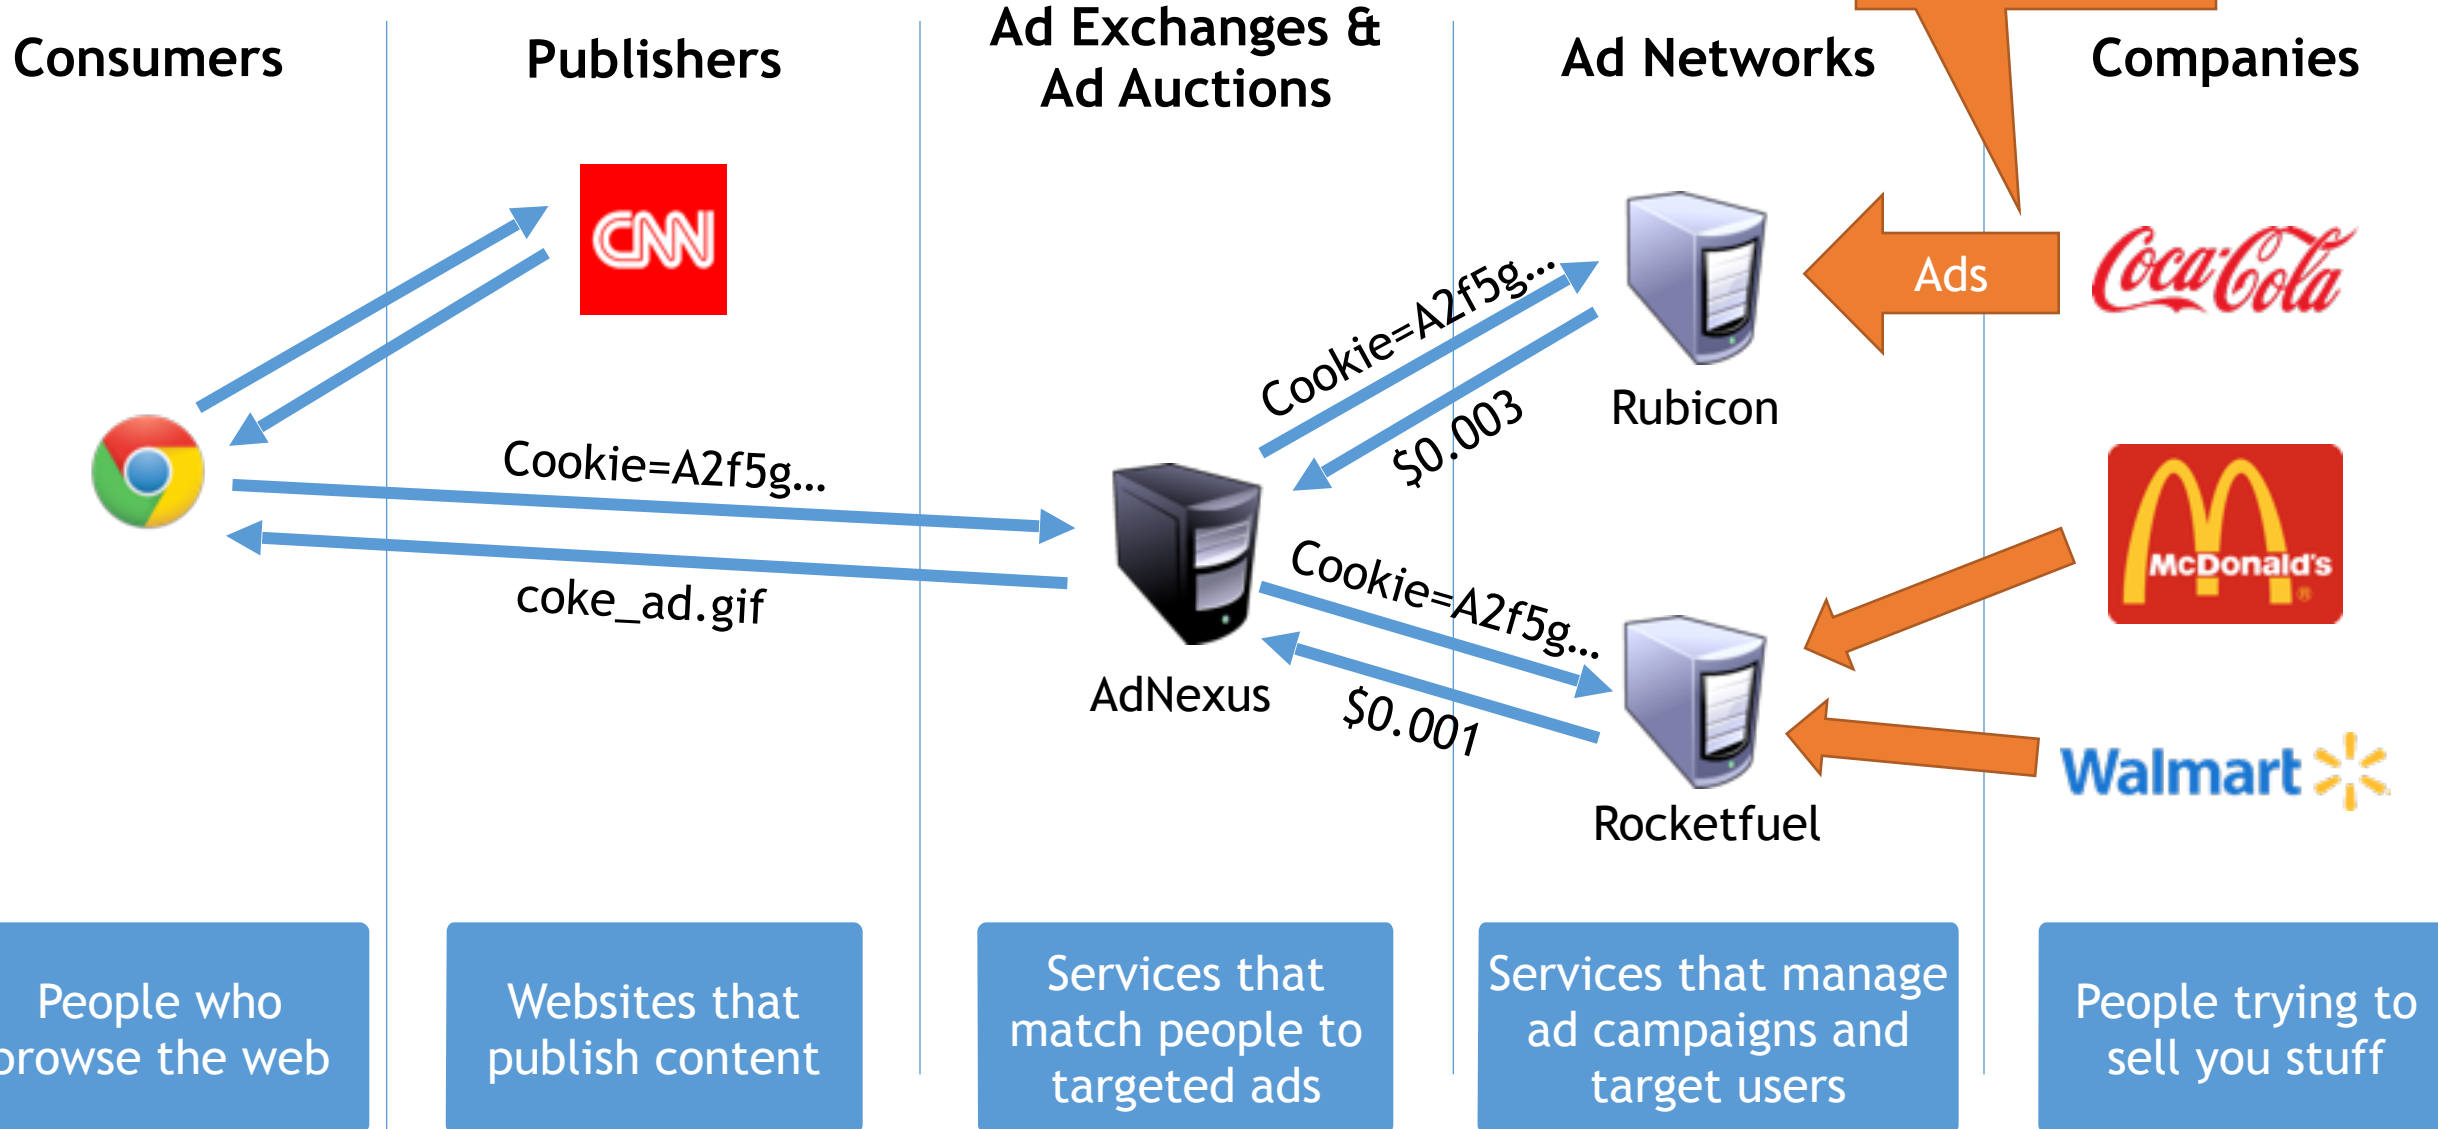

maps.google.com

Social Widgets

The Targeted Advertising Ecosystem

The Targeted Advertising Ecosystem

Consumers

People who browse the web

Publishers

Tracking data is stored and exchanged amongst these companies

Websites that publish content

Ad Exchanges & Ad Auctions

AdNexus

Services that match people to targeted ads

Ad Networks

Rubicon

Rocketfuel

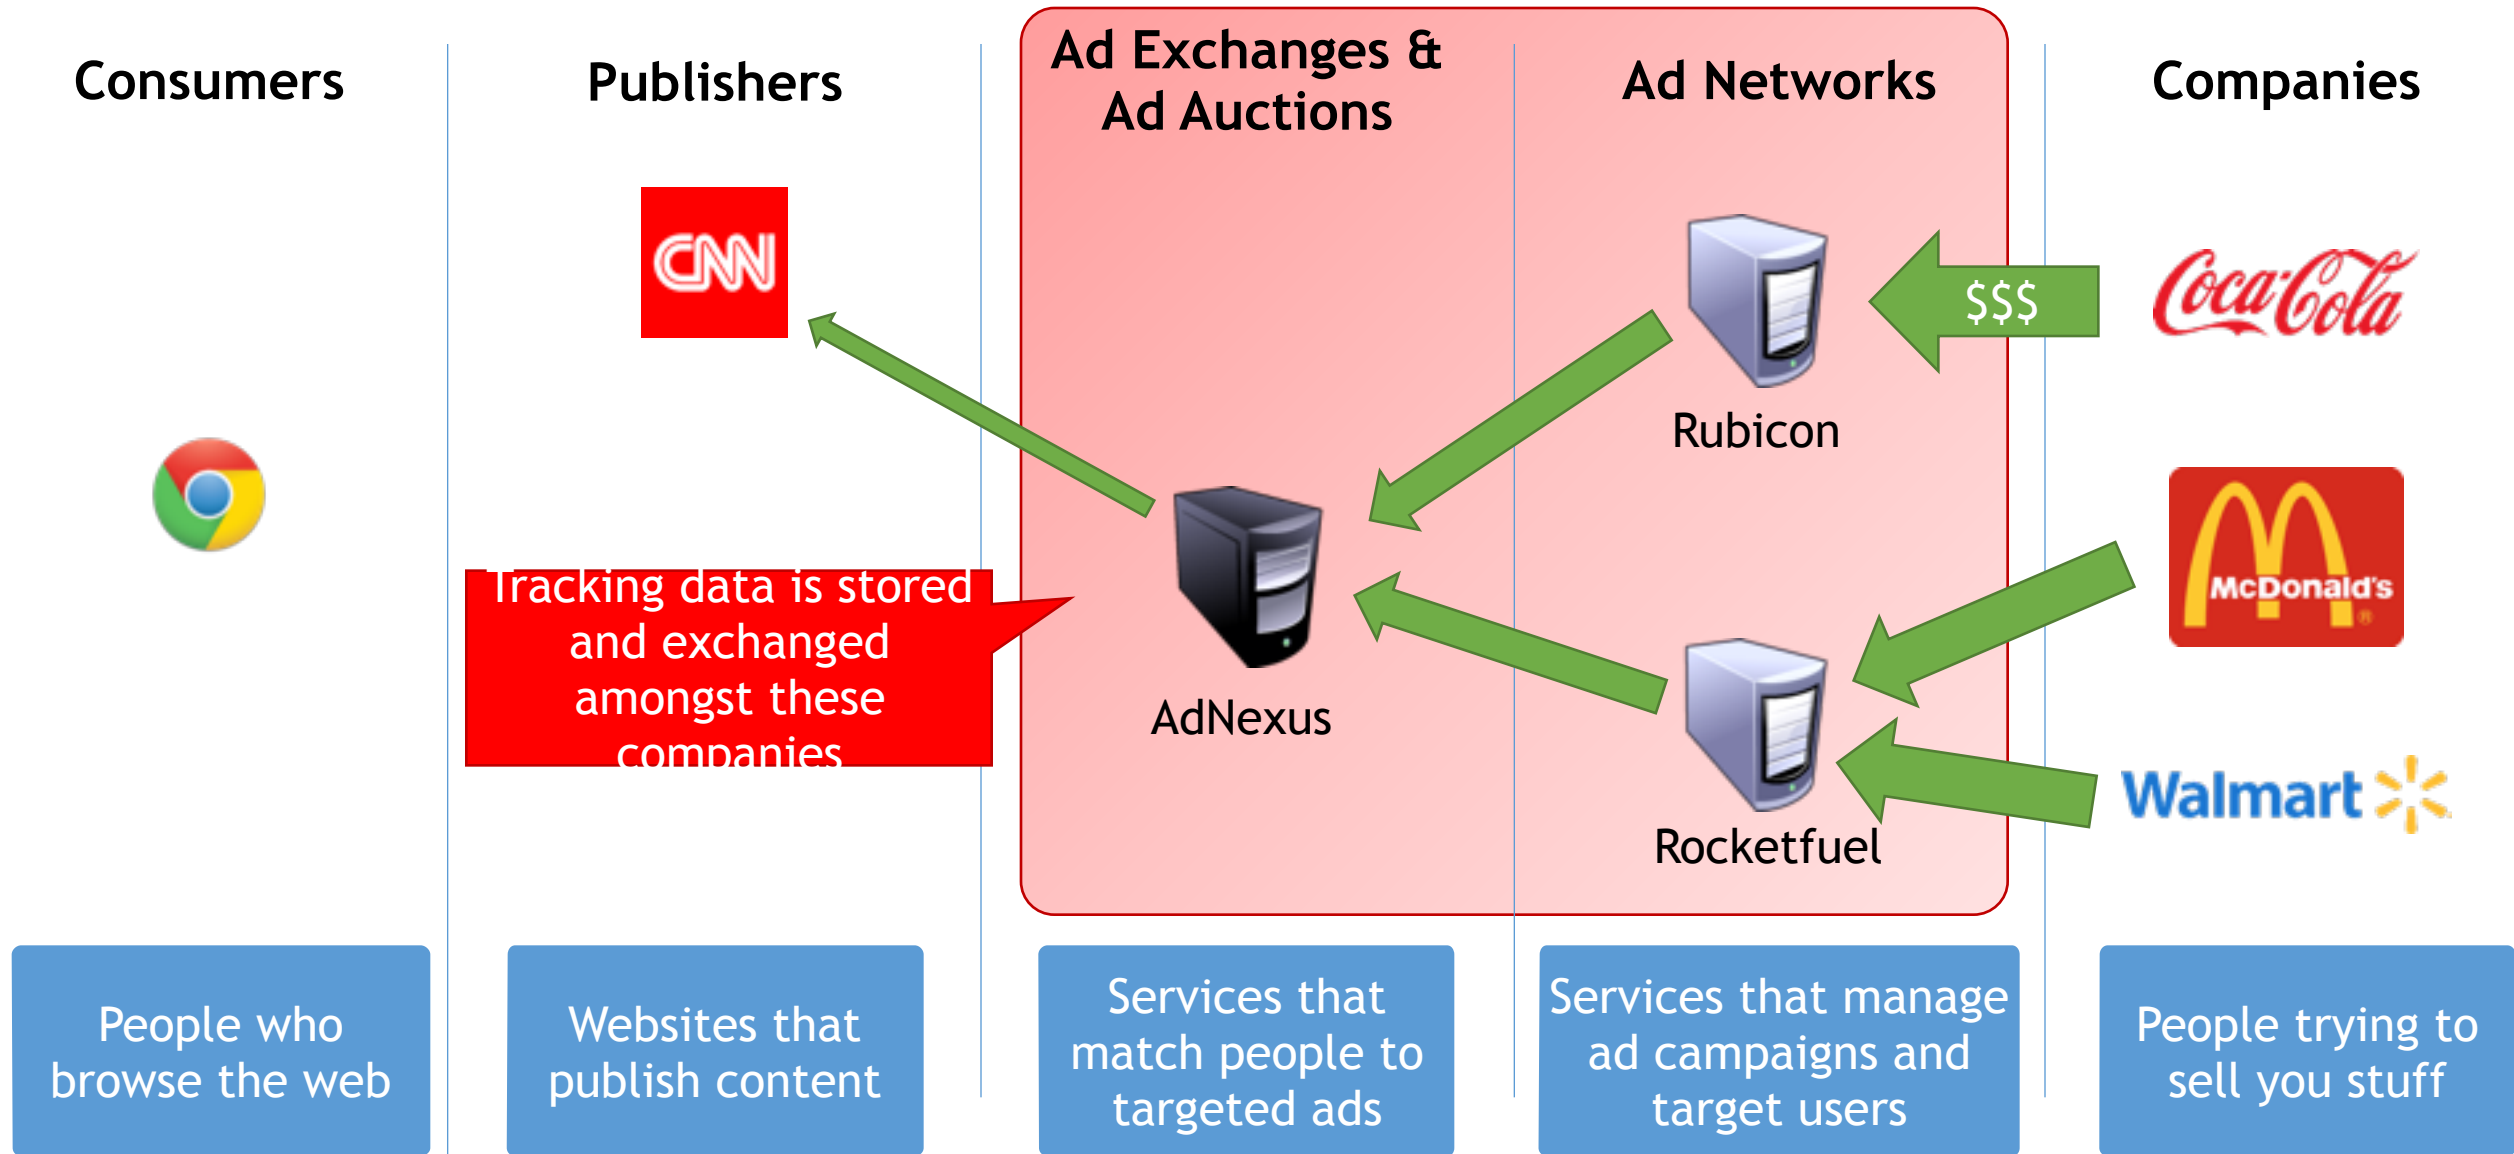

Services that manage ad campaigns and target users

Companies

People trying to sell you stuff

\$\$\$

Users Against Tracking Cookies

- Users did not respond well when they found out about tracking
- Many started clearing their cookies to avoid tracking
- Ad networks fought back using [Evercookies](#)
 - HTTP, HTML, and plugins provide many ways to store state on clients
 - Evercookies are placed in all available storage locations
 - If the cookie is deleted, it can be regenerated from the ‘backups’ in other locations

Evercookies

HTTP features

- Cookies
- E-tags - values set by the server that are supposed to be used for page caching
- Cached HTTP authentication credentials

HTML features

- window.name
- HTML5 localStorage
- HTML5 indexeddb
- HTML5 web database
- Web history (more on this later)

Plugins

- Flash Local Shared Objects (LSOs)
- Silverlight Isolated Storage
- Java PersistenceService

Mitigations Against Tracking Cookies

- **Opting-out**

- In an effort to stave off regulation, many online ad networks have voluntarily joined the AdChoices program
- AdChoices allows you to opt-out of some targeted advertising
- Ironically, the opt-out is stored as a cookie in your browser

- **Incognito/Private browsing mode**

- Starts a fresh browser instance with no cookies
- All cookies are erased when the instance closes
- Warning: plugins may still persist evercookie information

- **Extensions**

- Adblock, Ghostery, Disconnect, PrivacyBadger, NoScript, uMatrix

Do Not Track

- Proposed in 2009 by Christopher Soghoian, Sid Stamm, and Dan Kaminsky
 - HTTP header that informs third-parties you do not wish to be tracked
 - Supported by most modern browsers (but typically off by default)
- The original aim was get buy in from regulators and advertisers
 - Instead, the whole effort became controversial and politicized
 - Today, no laws or regulations mandate compliance with DNT
 - Digital Advertising Alliance does not require its members to honor DNT
- Issues
 - Microsoft attempted to set DNT: 1 by default in IE 10
 - Advertisers revolted and refused to support the initiative
 - What is the expected behavior of Do Not Track?
 - Can a third-party retain data for other purposes like analytics, debugging, or security audits?
 - Can an advertiser store data but simply not use it to target ads?

Beyond Tracking Cookies

- Times are getting tough for cookie-based tracking
 - Tracker-blockers are proliferating
 - Anti-cookie legislation/regulation are increasing
- Many advertisers are experimenting with cookie-less tracking
 - Otherwise known as [browser fingerprinting](#)

Your Browser is Unique

GET / HTTP/1.1

Host: www.google.com

Connection: keep-alive

Cache-Control: max-age=0

Accept: text/html

User-Agent: Mozilla/5.0 (Windows NT 6.3; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/42.0.2311.68 Safari/537.36

Accept-Encoding: gzip, deflate, sdch

Accept-Language: en-US,en;q=0.8

Cookie: _session=aAB4m3rf8weG224

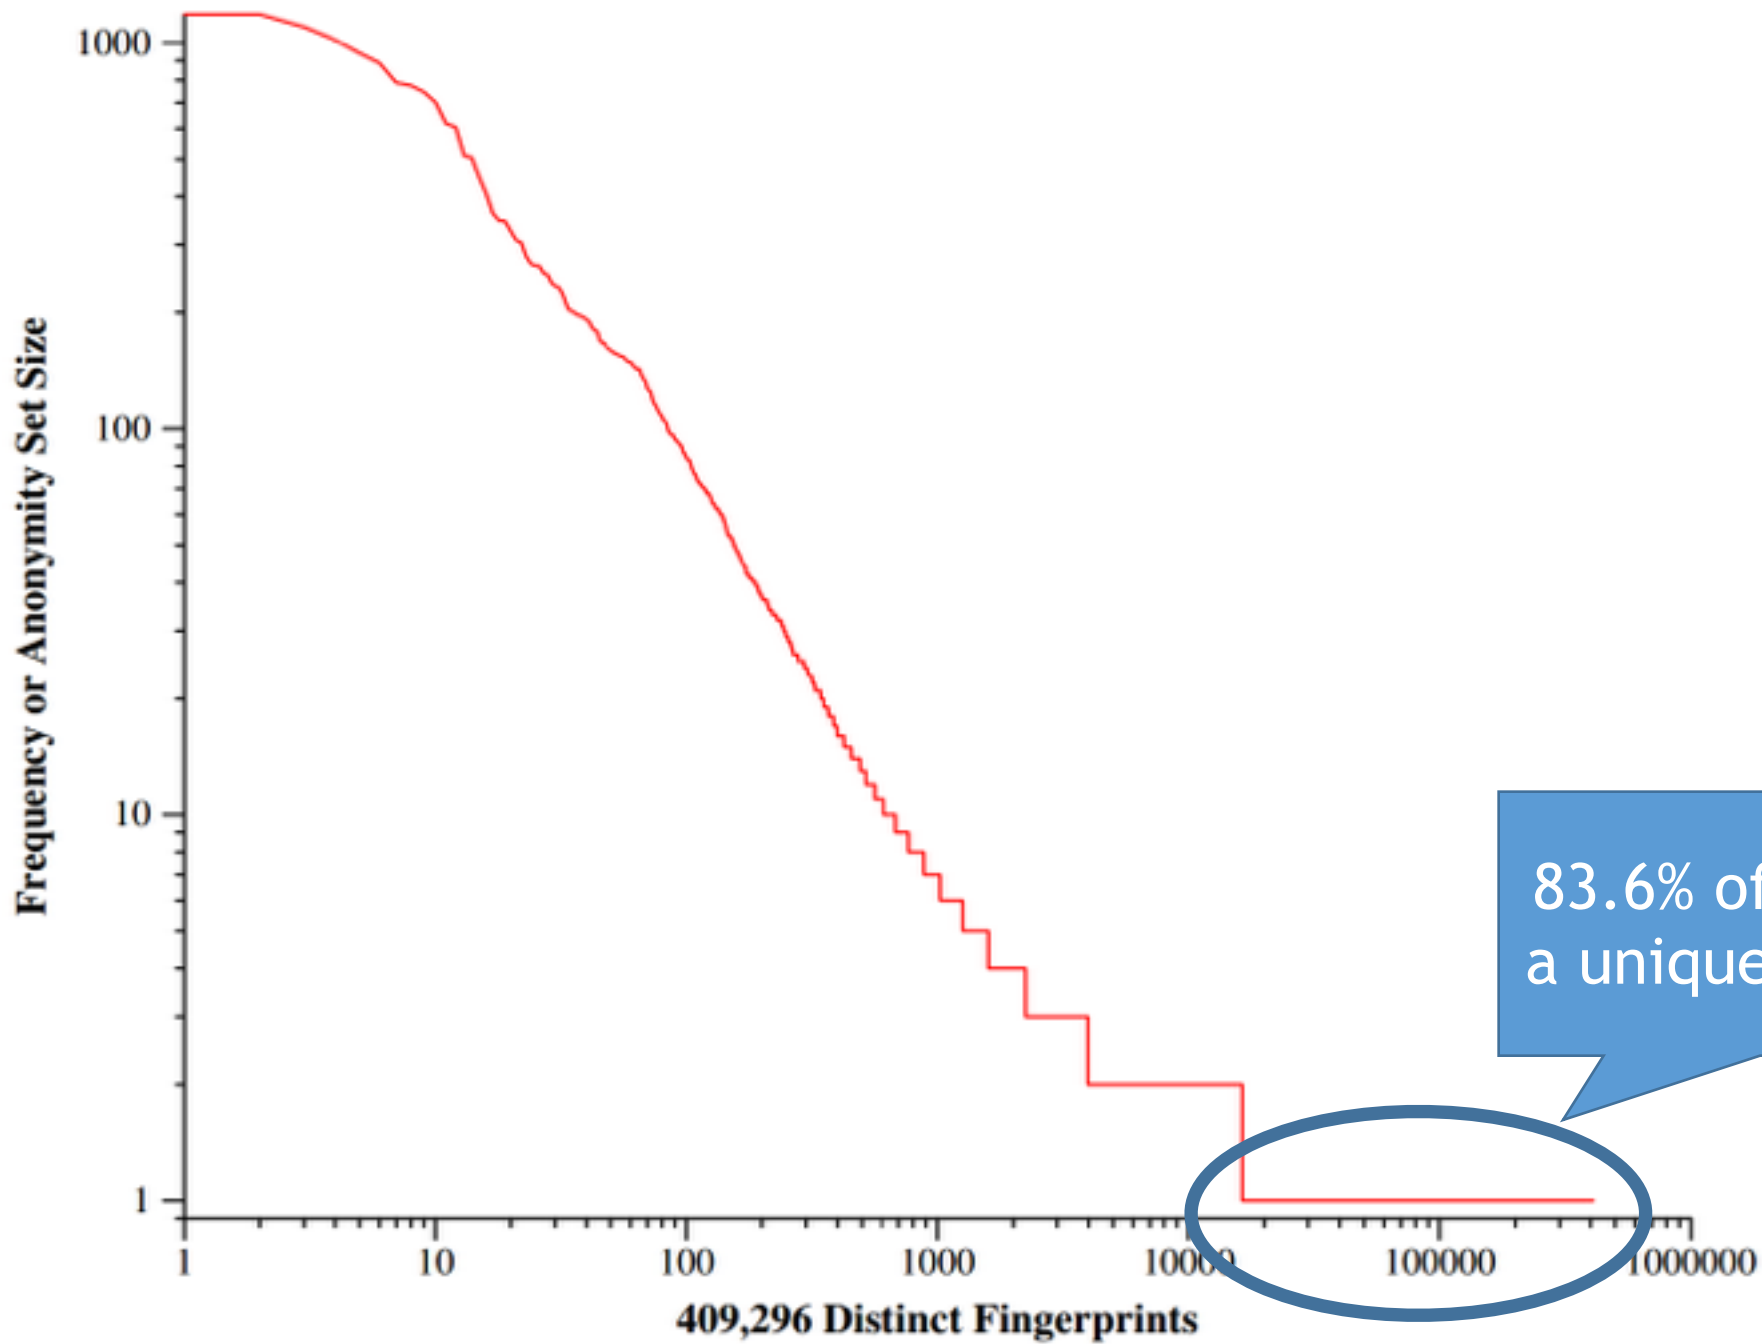

More Sources of Uniqueness

- Many more high-entropy characteristics are observable via Javascript/
plugins
 - What time zone are you in?
 - What fonts are installed on your machine?
 - What plugins are installed, and what are their versions?
 - What is your screen resolution and color depth?
 - Availability of specific JS APIs (i.e. browser version or platform dependent features)
 - Existence of specific browser extensions (e.g. Adblock)
 - Order in which HTTP headers are sent
 - Hardware-level characteristics like CPU ID and frequency (MHz)

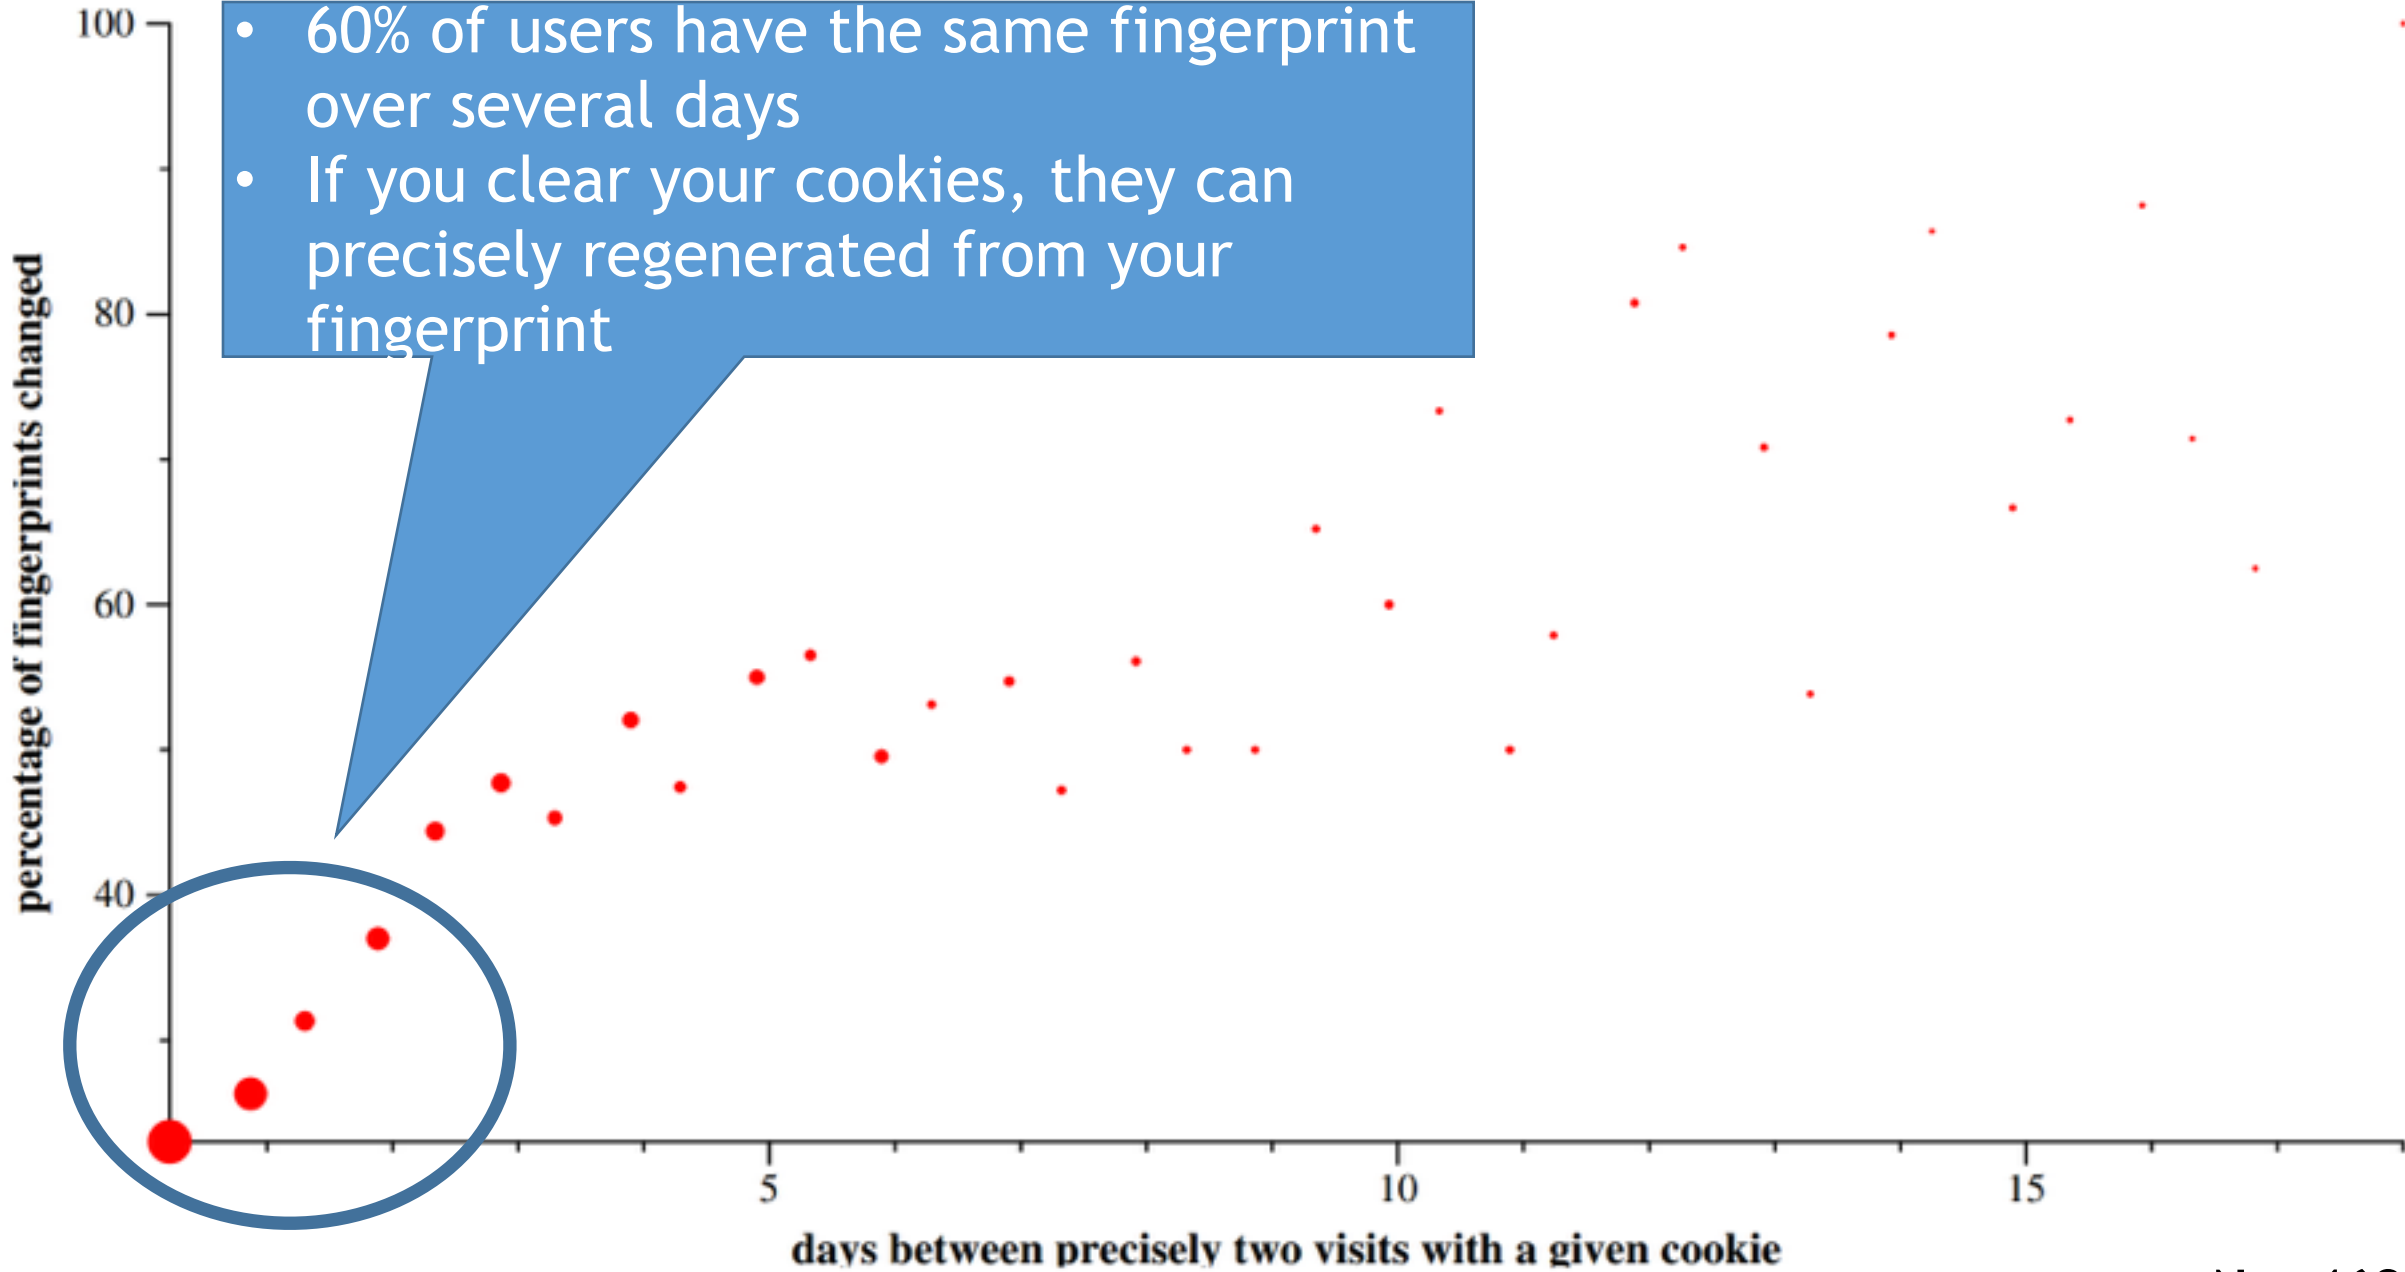

Browser Fingerprinting

- Fingerprinting is a method of identifying individual users based on the specific characteristics of their browser/system
 - Each characteristic is encoded as having bits of entropy
 - 15-20 total bits of entropy is enough to uniquely identify most people
- Examples:
 - Is Javascript enabled? - Roughly .4 bits of entropy (on or off, but off is much less common)
 - User-Agent? - Roughly 19 bits of entropy (OS → browser → version)
- Test yourself: <https://panopticklick.eff.org/>

83.6% of users have a unique fingerprint

- 60% of users have the same fingerprint over several days
- If you clear your cookies, they can precisely regenerated from your fingerprint

Canvas Fingerprinting

- Fingerprinting techniques are becoming more sophisticated
- Canvas fingerprinting
 - Leverages a hidden HTML5 <canvas>
 - Javascript renders text and drawing using various styles and fonts
 - The bitmap is then converted into a unique token
- Entropy is due to OS, browser, GPU, and graphics driver
 - Experiments observed 5.7 bits of entropy via canvas fingerprinting
 - True entropy is likely higher
- In 2014, many sites and ad trackers were caught using canvas fingerprinting

Canvas Fingerprinting Example

Cwm fjordbank glyphs vext quiz

<http://valve.github.io>

<http://admicro.vn/>

<http://www.plentyoffish.com>

ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz0123456789+/-

Mitigations Against Fingerprinting

- Adding more entropy into the browser
 - Example: uMatrix can randomize your User-Agent
 - Randomize the order of HTTP headers
- Reduce or restrict browser functionality
 - Cap the number of fonts a given page may query
 - Cap the number of plugins a given page may invoke
- Problem: some things cannot be randomized, removed, or restricted
 - Time zone and language cannot be randomized in general
 - Access to new Javascript APIs

History Stealing

CSS :visited

Timing Attacks

Story So Far

- Attacks thus far have been about inferring individual identity
 - Cookies and fingerprints
- What about attacks that try to infer your behavior
 - Specifically, your browsing history
 - Useful information for marketers and traditional attackers
 - E.g. do you have an account at BofA or a credit card with Chase?

Let's Talk About Hyperlinks

Visited
Link

www.slashdot.org

www.reddit.com

www.webmd.com

www.chase.com

www.bankofamerica.com

Unvisited
Link

```
var links =
document.querySelectorAll('a');

for (var x = 0; x < links.length; ++x) {
  console.log(
document.defaultView.getComputedStyle(
  link[x], null
  ).color
);
}
```

```
>> rgb(85, 26, 139)    # Purple
>> rgb(0, 0, 238)     # Blue
>> rgb(85, 26, 139)    # Purple
>> rgb(85, 26, 139)    # Purple
>> rgb(0, 0, 238)     # Blue
```

History Stealing via CSS :visited

- Simple method to steal someone's browsing history
 1. Send the victim to a page that includes malicious JavaScript *J*
 - Alternatively: use XSS to inject malicious JS into a benign website
 2. *J* creates a list of `<a>` tags on the page
 - List is composed of links to well known sites
 - List can be hidden off-screen or using Javascript so the user is unaware
 3. *J* iterates through the list of anchors and examines their colors
 - Any purple links have been browsed by the victim

History Stealing via Timing Attack

- Observation: it takes browsers longer to render visited links than unvisited links
 - Unvisited: draw the link, `has_link_been_visited() == false`, move on
 - Visited: draw the link, `has_link_been_visited() == true`, draw the link again
- 1. Send the victim to a page that includes malicious JavaScript *J*
 - Alternatively: use XSS to inject malicious JS into a benign website
- 2. *J* injects `<a>` tags into the page one at a time
 - List is composed of links to well known sites
 - List can be hidden off-screen or using Javascript so the user is unaware
- 3. *J* measures the time taken to draw each link
 - Calculate average draw-time by injecting links to non-existent pages
 - Links with draw-time significantly above the average have been visited

Mitigations Against History Stealing

- Basic approaches
 - Clear your history, or configure your browser to not store history
 - Disable styling of visited links
 - Disable Javascript
- Fixes implemented by Mozilla in 2010
 - CSS may only alter specific properties of `:visited` links versus `:unvisited`
 - Foreground and background color, outline, border, SVG stroke, and fill color
 - None of these properties impact the size or layout of surrounding elements
 - Javascript may no longer read certain style properties of links
 - All links appear to have unvisited colors
 - Changes to the rendering engine to make all links render in equal time

Final Thoughts

- Your personal information is valuable
 - Companies want it, attackers want it
- Your browser is a complex state machine that allows third-parties to run (somewhat) arbitrary code
 - Obvious and non-obvious mechanisms for tracking you personally...
 - ... as well as your browsing history
- There is no silver bullet for privacy on the Web
 - Technological measures can help (modified browsers + extensions)
 - Eventually, regulatory mechanisms will also be necessary
